Description

The present invention relates to a novel way of joining a nucleic acid to a solid substrate so as to provide a solid probe suitable for use in various tests, particularly hybridization assays for the determination of specific polynucleotide sequences.

In DNA-DNA hybridization and DNA-RNA hybridization assays, one of the complementary nucleic acid chains is commonly coupled to a solid support. This helps to reduce the background and can be used to separate or isolate the corresponding nucleic acid. The methods of attachment of DNA to a solid support have involved (1) non-specific physical adsorption of a single-stranded DNA to nitrocellulose papers, and (2) covalent attachment via diazo coupling. Both methods are specific for single-stranded DNA. These covalent reactions are non-specific and several sites are coupled. These cause ineffective hybridization and loss of perfect fidelity. Several points of attachment per chain reduces the flexibility of the DNA and reduces the rate of hybridization. Moreover, the lifetime of such an adduct is not very long. The DNA comes off easily and it is difficult to quantify the amount on the solid support, without the use of radioactivity. The use of DNA probes for diagnostic purposes demands an effective method of tagging the DNA to a phase which can be separated easily from the rest of the nucleic acids.

In Chemical Abstracts, Vol. 98, No. 9 (1983) page 315, No. 68377g an immobilization of denatured DNA to macroporous supports is described with either a diazo coupling or BrCN. Chemical Abstracts, Vol. 96, No. 5, (1982), page 310, No. 31231n refers to coupling of nucleic acids on support material by using cyan uric acid as coupling agent.

EP—A—130 515 discloses various tests for nucleic acids; e.g., DNA of individuals being tested for sickle cell anemia. The test involves a soluble labelled probe and a probe fixed to a solid support. The probe can be fixed to the support chemically as by a bifunctional reagent which at one end reacts with the support, e.g., a hydroxyl group of a cellulose molecule, and at the other end reacts with the DNA. This is quite satisfactory for many purposes but in some instances there may be too much bonding between the substrate and DNA, impairing the sensitivity of the DNA in the test.

It is accordingly an object of the present invention to provide a way of binding a nucleic acid to a solid substrate easily and without impairing the sensitivity of the DNA in the test.

These and other objects and advantages are realized in accordance with the present invention wherein there is provided a solid support capable of binding a nucleic acid thereto upon suitable irradiation, comprising (a) a solid substrate, (b) a photochemically reactive nucleic acid-binding ligand, and (c) a divalent radical chemically linking the substrate and the nucleic acid-binding ligand.

The specific coupling reagents employed are functionalized, photochemically reactive nucleic acid-binding ligands, e.g., intercalator compounds such as amino-substituted furocoumarins, e.g., amino-methyl-dimethyl-angelicin and amino-methyl-trimethyl-psoralen, and aminophenanthridium halides as well as closely related chemical derivatives thereof, and non-intercalator compounds such as netropsin, distamycin, Hoechst 33258® and bis-benzimidazole. Upon photoactivation these reagents will chemically link with nucleic acids. These reagents have a functionalized site other than the nucleic acid-reactive site and, by such other site, they are joined to a solid substrate, thereby in turn joining the nucleic acid to such substrate with a minimum impairment of the nucleic acid function.

Apparently functionalized and photochemically reactive forms of a wide variety of intercalating agents can be used as the coupling reagent as exemplified in the following table:

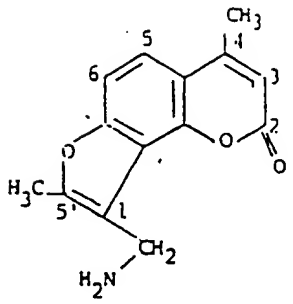
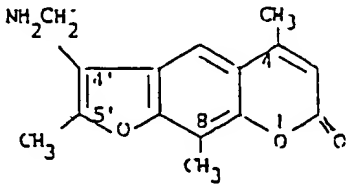
Angelicin, more accurately 4'-aminomethyl-4,5'-dimethylangelicin, has the structural formula



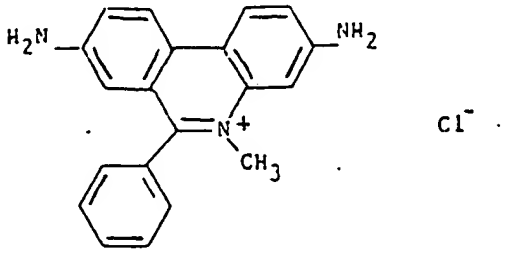
(see Dall'Acquz et al, Photochemistry and Photobiology, Vol. 37, No. 4, pp. 373—379, 1983).

Psoralen, more accurately 4'-aminomethyl-4,5',8-tri-methyl-psoralen (AMT), has the structural formula

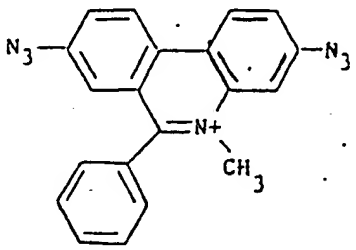


(Cadet et al, Photochemistry and Photobiology, Vol. 37, No. 4, pp. 363—371, 1983).

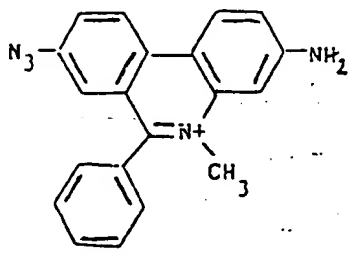
Methidium chloride, for example, has the formula



(see Graves et al, Biochemistry, 1981, Vol. 20 pp. 1887—1892). Its mono- and di-azide analogues, shown below, are comparably reactive:



methidium monoazide



methidium diazide

as are the ethyl counterparts and the 4-(3-aminopropyl-N-carbamoyl) derivative of the phenyl side chain (methidium propylamine).

The solid substrate can be any solid which has reactive groups which could be carboxyl, amino or the like, but the preferred reactive groups are hydroxyl such as are found on cellulose. The cellulose may be unmodified as in cotton or paper or regenerated as in rayon or partially esterified as in cellulose acetate, cellulose propionate and especially cellulose nitrate, or partially etherified as in methylcellulose and carboxymethylcellulose.

While the photochemically active intercalator reagent could be directly combined with the solid substrate, advantageously there is a mutual coupler which makes the connection. Suitable reagents include bifunctional compounds such as cyanogen bromid (CNBr), 1,4-butanediol diglycidyl ether, and the lik . These are reacted with both the solid substrate and th photochemical reagent simultaneously or first with one and then with th other.

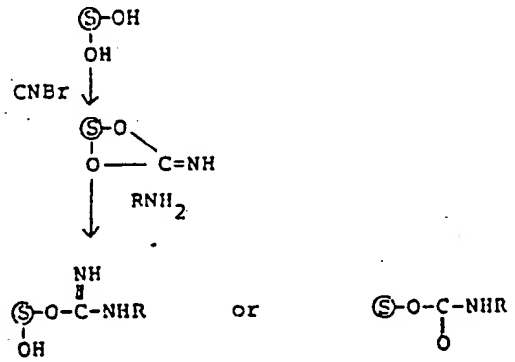
Thereafter, th product is further reacted with the nucl ic acid ph tochemically. The r actions with the coupler and nucleic acid are substantially quantitative so the quantities of th reagents empl yed depend

upon the desired ratio of nucleic acid to solid support. For most purposes, about 0.1 to 1000 mg and preferably about 1 to 100 mg of nucleic acid per gram of solid support will be suitable, although it may be higher or lower, depending upon the molecular weight of the nucleic acid, its sensitivity and the particular test in which it is to be used.

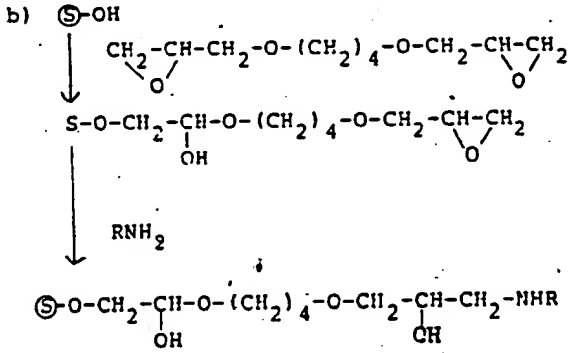
The reaction conditions in each step are generally known per se and any solvents and temperatures can be employed which permit the reactions to proceed without interference, e.g., from about −10 to 100°C., preferably about 10 to 50°C., and most preferably room temperature, employing inert organic solvents such as ether, carbon tetrachloride, THF, and the like.

The photochemically active reagents herein employed preferably react through amino groups. Identifying it as RNH_2 and the substrate with pendent OH groups as S, the stepwise reactions are as follows:

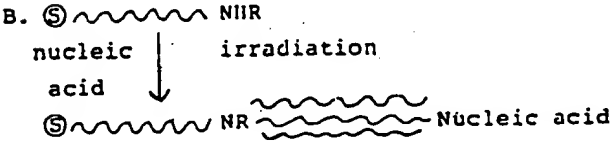
A. a) with CNBr



b)



B.



Amino-derivatives of angelicin and psoralen react correspondingly, if not identically.

The particular wavelength or radiation selected will depend upon the particular photoreagent and whether it is desired to bind to a single strand of nucleic acid or to a double strand. If to both strands it can be in a manner and to a degree such that the nucleic acid is no longer denaturable.

The nucleic acid can be RNA or DNA of short (oligonucleotide) or long chain length, as desired, doubly or singly stranded.

Formation of monoadducts is desirable for hybridization experiments. In crosslinks, both DNA strands are covalently linked to psoralen chromophore and hence strand separation prior to hybridization is difficult. If the probe to be hybridized is linked to another non-specific piece of DNA, the non-specific part can be linked either via crosslink or monoadduct formation. In this case, irradiation can be done at any wavel ngths between 300—390 nm. Irradiation at 390 nm produces monoadduct; irradiation at 360—300 nm produces both monoadduct and crosslinks.

If angelicin compounds are used, the product will predominantly be monoadduct irrespective of the wav length of irradiation.

The invention will now be further described with reference to the accompanying examples wherein all parts are by weight unless otherwise expressed.

Example:

1. Activation of the solid support and coupling of AMT

The procedure described below has been folowed for Sephadex®G25 and cellulose, but any hydroxy-containing solid support can be activated by an identical procedure.

a) Activation with 1,4-butane-diol-diglycidyl ether

0.5—1 gm solid powder is swollen with water and washed, then 5—10 ml sodium hydroxide solution (0.5 M) is added. To this thick suspension, 1 ml 1,4-butanediol-diglycidyl ether is added. The suspension is shaken overnight on a mechanical shaker and then washed with sodium hydroxide (0.5 M) solution and 1.0 ml 4'-aminomethyl-4,5',8-trimethyl-psoralen (2 mg/ml) in water is added, followed by enough 1 M sodium hydroxide to have a thick suspension. The suspension is then stirred gently for 24 hours at room temperature and excess unreacted residues are quenched with lysine.

The solid is then washed with water followed by the desired aqueous buffer solution for DNA coupling.

b) For epoxidation of paper the identical procedure is followed with Whatman filter papers type 540, 1 and 541. The filter papers are taken on a watch glass or beaker cover (glass) and turned occasionally by hand. The rest of the procedure is the same as above.

c) Activation by cyanogen bromide and coupling of AMT. Typical example with cellulose:

0.5 gm cellulose is swollen in 5.0 ml distilled water for one hour. The swollen gel is washed thoroughly with distilled water. Then it is taken in an erlenmeyer flask, ice-cooled distilled water is added to the swollen cellulose and the pH is adjusted between 10.5—11 with 5M sodium hydroxide solution. The flask with its contents is cooled in ice to avoid temperature rise above 15°C. 1 gm of solid cyanogen bromide is added to the cellulose and the solution is stirred for 30 minutes and pH maintained between 10.5—11 by NaOH. The suspension is washed with ice cold distilled water, water is removed by centrifugation and 20 ml ice cold potassium phosphate buffer (10 mM; pH 8) is added. The activated cellulose is kept in brown bottles (in small aliquots) at −20°C.

2—3 ml of swollen, activated gel is taken in a brown bottle and 0.7 ml AMT (2mg/ml) is added and the mixture is shaken gently in the cold room. Excess activated residues are quenched with lysine. The solid is washed with aqueous buffer for DNA binding.

d) For papers, similar procedures have been followed with Whatman cellulose filter papers type 540, 1 and 541 quantitative papers. Care should be taken to avoid tearing of the papers.

e) Parallel experiments with ^3H labelled aminomethylpsoralen or angelicin are used to estimate labelling efficiency.

2. Coupling of phenanthridium compounds to a solid support and azide formation for photochemical coupling of DNA:

Activation of the solid supports is done by the method described above. As an example, methidium propylamine (R.P. Hertzberg and P.B. Dervan, JACS, *104*, 313 (1982)) is coupled to the solid support, using identical buffer conditions as in 1. The isolated methidium containing solid support is then diazotized and azide derivative is made as follows. 1 gm cellulose or (2 × 5 cm^2) of a sheet of activated paper containing methidium chloride is taken in 20 ml water, cooled in ice, 0.2 ml ice cold HCl is added; sodium azide (20 mg solid; 2 ×) is added. The vessel is cooled in ice and sodium nitrate solid (100 mg) is added. The reaction is allowed to proceed for 30 minutes, solid support is washed with the desired buffer. Coupling of DNA and hybridization are carried out the same way as described for aminomethyl-psoralen. Aminomethyldimethyl-angelicin can be similarly treated.

3. Photochemical coupling of DNA:

0.5 ml (0.2 − 0.3 gm gel + buffer) activated solid powder or 0.8 × 1 cm^2 activated paper is taken in a 1 cm path length spectrophotometer cuvette. Adenovirus DNA (partially labelled with ^3H) (concentration 25 µg/ml) in tris EDTA buffer (10 mM tris, 1 mM EDTA, pH 7.5) is added to the cuvette and irradiation is done at a desired wavelength for 30 minutes to two hours depending on the future needs. For AMT, irradiation at 390 nm produces monoadduct whereas at 360—300 nm both monoadduct and crosslinks are formed. By altering the concentration and DNA sequence, crosslink to monoadduct formation can be modulated. After photoirradiation, the solid is washed and the radioactivity of the washings and the solid support is counted in a Beckman 7800 scintillation counter.

Typical Results

Solid support	% Coupling	DNA Coupled µg
0.5 ml or 0.8 × 1 control paper (No DNA)	—	—
BDGE treated paper	80	20
Cellulose cellex CNBr activated	91.5	22.5
Cellulose cellex BDGE activated	93.4	22.5
Sephadex®G25 CNBr activated	69.5	18.0

4. Assay for DNA-DNA hybridization of DNA photochemically coupled to the solid support:

Andenovirus DNA is covalently coupled to the solid support as above and hybridization with ^3H labelled adenovirus DNA is done following the procedure of Noyes and Stark, Cell, *5*, 301—310 (1975).

5. Use of photochemically coupled DNA for sickle cell diagnosis:

AMT coupled DNA can be recovered as free DNA by irradiation at 260 nm. The separation probe European Patent Application No. 130 515 is coupled to the solid support by the method described above. Then the support with the coupled DNA is mixed with the unknown and the detection probe under hybridization condition — as in 4. The solid support is then tested for the presence of label. If a radioactively labelled detection probe is used, radioactivity is counted.

5a. The product of 4 is irradiated at 260 nm in otherwise the same manner as in 3, whereupon the DNA uncouples from the solid support, entering the solvent medium, viz. aqueous buffer. Then the liquid is assayed for ^3H.

It will be understood that the specification and examples are illustrative but not limitative of the present invention and that other embodiments within the scope of the invention will suggest themselves to those skilled in the art.

Claims

1. A solid support capable of binding a nucleic acid thereto upon irradiation, comprising (a) a solid substrate, (b) a photochemically reactive nucleic acid-binding ligand, and (c) a divalent radical chemically linking the substrate and the nucleic acid-binding ligand.

2. A support according to claim 1, characterized in that the nucleic acid-binding ligand is an intercalator compound selected from acridine dyes, phenanthridines, phenazines, furocoumarins, phenothiazines, and quinolines.

3. A support according to claim 1 or 2, characterized in that the substrate (a) in free state has free OH groups through which it is linked by the divalent radical (c).

4. A support according to any of claims 1 to 3, characterized in that the substrate (a) is cellulose or a cellulose ester.

5. A support according to any of claims 1 to 4, characterized in that the divalent radical (c) is derived from cyanogen bromide or from 1,4-butanediol-diglycidyl ether.

6. A support according to any of claims 1 to 5, characterized in that (b) is psoralen, angelicin, ethidium or derivatives thereof.

7. An immobilized nucleic acid probe wherein the nucleic acid is photochemically linked to the nucleic acid-binding ligand (b) of any of the solid supports of claims 1—6.

Patentansprüche

1. Fester Träger, der bei Bestrahlung in der Lage ist, eine Nucleinsäure zu binden, enthaltend (a) ein festes Substrat, (b) einen fotochemisch reaktiven, Nucleinsäure bindenden Liganden, und (c) einen zweiwertigen Rest, der das Substrat und den Nucleinsäure bindenden Liganden chemisch verknüpft.

2. Träger gemäss Anspruch 1, dadurch gekennzeichnet, dass der Nucleinsäure bindende Ligand eine Intercalatorverbindung, ausgewählt aus Acridin-Farbstoffen, Phenanthridinen, Phenazinen, Furokumarinen, Phenothiazinen und Chinolinen, ist.

3. Träger gemäss Anspruch 1 oder 2, dadurch gekennzeichnet, dass das Substrat (a) in freiem Zustand freie OH-Gruppen aufweist, durch welche es mittels des zweiw rtigen Rest s (c) verknüpft ist.

4. Träger gemäss ein m der Ansprüche 1 bis 3, dadurch gekennzeichnet, dass das Substrat (a) Zellulose oder ein Zellulos ester ist.

5. Träger gemäss inem der Ansprüche 1 bis 4, dadurch g kennzeichnet, dass der zweiwertige Rest (c) sich von Bromcyan der 1,4-Butandi ndiglycidyl ther ableitet.

6. Träger gemäss einem der Ansprüche 1 bis 5, dadurch gekennzeichnet, dass (b) Psoralen, Angelicin, Ethidium oder ein Derivat davon ist.

7. Eine Sonde für eine immobilisierte Nucleinsäure, in welchem die Nucleinsäure fotochemisch an den Nucleinsäure bindenden Liganden (b) durch einen der festen Träger gemäss Ansprüchen 1 bis 6 gebunden ist.

Revendications

1. Un support solide capable de se lier à un acide nucléique par irradiation, comprenant (a) un substrat solide, (b) un ligand de liaison d'acide nucléique photochimiquement réactif et (c) un radical divalent liant chimiquement le substrat et le ligand de liaison d'acide nucléique.

2. Un support selon la revendication 1, caractérisé en ce que le ligand de liaison d'acide nucléique est un composé intercalant choisi parmi les colorants d'acridine, les phénanthridines, les phénazines, les furocoumarines, les phénothiazines et les quinoléines.

3. Un support selon la revendication 1 ou 2, caractérisé en ce que le substrat (a) à l'état libre a des groupes OH libres par lesquels il est lié par le radical divalent (c).

4. Un support selon l'une quelconque des revendications 1 à 3, caractérisé en ce que le substrat (a) est en cellulose ou en ester de cellulose.

5. Un support selon l'une quelconque des revendications 1 à 4, carctérisé en ce que le radical divalent (c) dérive du bromure de cyanogène ou de l'éther diglycidylique du 1,4-butanediol.

6. Un support selon l'une quelconque des revendications 1 à 5, caractérisé en ce que (b) est le psoralène, l'angélicine, l'éthidium ou leurs dérivés.

7. Une sonde d'acide nucléique immobilisé dans laquelle l'acide nucléique est lié photochimiquement au ligand (b) de liaison d'acide nucléique de l'un quelconque des supports solides des revendications 1 à 6.
